KEY WORDS: FLIM, FRET, tumor, NADH

While laser scanning fluorescence lifetime imaging (FLIM) is a powerful approach for cell biology, its small field of view (typically less than 1 mm) makes it impractical for imaging of large objects that is often required for biomedical applications. In this talk, we present a system that allows to perform both fluorescence and phosphorescence lifetime imaging (FLIM/PLIM) on macroscopic samples as large as 18 mm with a lateral resolution of 15 µm. We verified the performance of the system by doing FLIM of endogenous metabolic cofactor reduced nicotinamide adenine dinucleotide (phosphate), NAD(P)H, and genetically encoded fluorescent protein mKate2 in a mouse tumor in vivo. Moreover, by using PLIM we managed to observe the oxygen status of healthy and tumor areas in live animals. We used the genetically encoded sensor TR23K based on the red fluorescent protein TagRFP and chromoprotein KFP linked by 23 amino acid residues (TagRFP-23-KFP) containing a specific caspase cleavage DEVD motif to monitor the activity of caspase-3 in tumor xenografts by means of fluorescence lifetime imaging-Forster resonance energy transfer during chemotherapy with paclitaxel. Time-resolved macroscopic imaging proves to be a nice method not only for exploration biological processes in vivo in the whole tumor, but also for drug screening, facilitating the development of new anticancer agents as well as improvement of chemotherapy efficiency and its adaptation for personal treatment.
